The artifact I’m focusing on is my mobile event-tracking app from CS 360. It lets users create, view, edit, and delete events, saving all the information in a database. I built it during my course. I chose this artifact because I wanted to enhance its database capabilities. I added event searching, filtering, and sorting, along with database indexes to improve performance. These improvements showcase my skills in Java, SQL, databases, and software development. I met the objectives I aimed for in Module One. These enhancements showed my ability to upgrade a database and use it effectively to store, retrieve, and organize information. I didn’t change my original outcome-coverage plan significantly. While enhancing the app, I learned more about SQL queries, database indexing, and how to connect database features to the user interface. One challenge I faced was ensuring that the database changes didn’t erase any existing event information. Overall, this project made me more comfortable with improving an existing application and adding new features.
